MSc in Data Science for Health and Social Care

Applied Research Design in Data Science for Health and Social Care assignment: Research Proposal

Exam Number: B248593

Word Count: 2494

1. Study title

How can AI-based posture recognition using Convolutional Neural Networks (CNNs) be applied to detect and analyze habitual patterns of human movement and posture in relation to the concept of 'use of the self' in the Alexander Technique?

2. Lay summary

This research explores how computer programs can be used to find patterns in how people move and hold themselves in everyday life, based on the idea of 'the use of the self' from the Alexander Technique. The Alexander Technique is a method that helps people become more aware of their posture and movement habits, which can affect overall wellbeing, tension, and coordination. By using advanced posture recognition powered by artificial intelligence—specifically Convolutional Neural Networks (CNNs)—this study aims to detect these patterns from videos of participants during natural movement tasks.

This project will analyze existing video data from Palermo et al. (2021) called the Multi-View Gait and Posture Dataset, which is available on. The dataset includes recordings of individuals walking and standing, captured from multiple angles under controlled conditions. The aim is to explore whether AI can identify physical habits and changes related to posture, informed by the principles of the Alexander Technique.

This could contribute to efforts aimed at improving movement awareness and developing accessible methods for preventing musculoskeletal issues. The secondary data will be used in compliance with the dataset's licensing terms and associated ethical guidelines to ensure responsible and privacy-conscious research conduct.
